Resistance Monitor

Measured Resistance: 190.75 Ohms

Figure 1.2.10.1: Website

1.2.5. Explanation

1.2.1. We create a variable called analogPin and assign it to 0. This is because the voltage value we are going to read is connected to analogPin GPIO34.

1.2.2. The 12-bit ADC can differentiate 4096 discrete voltage levels, 5 volt is applied to 2 resistors and the voltage sample is taken in between the resistors. The value which we get from analogPin can be between 0 and 4095. 0 would represent 0 volts falls across the unknown resistor. A value of 4095 would mean that practically all 5 volts falls across the unknown resistor.

1.2.3. V_{out} represents the divided voltage that falls across the unknown resistor.

1.2.4. The Ohm meter in this manual works on the principle of the voltage divider shown in Fig. 1.2.3.1.

$$V_{out} = \frac{R_1}{R_1 + R_2} V_{in} \quad (1.2.4.1)$$

$$\Rightarrow R_2 = R_1 \left(\frac{V_{in}}{V_{out}} - 1 \right) \quad (1.2.4.2)$$

In the above, $V_{in} = 5V$, $R_1 = 220\Omega$.

1.2.5. Repeat the exercise with another unknown resistance.
